#### (57) Abstract

This invention describes that apoptin fails to induce apoptosis in human normal cells. Besides, the invention describes that when normal cells are transformed, they become susceptible to the apoptin-induced apoptosis. The invention describes that apoptin induces in various human tumor cells a p53-distinct type of apoptosis, and cannot be blocked by a variety of apoptosis-inhibiting agents. The invention comprises an anti-tumor agent, which specifically kill tumor and not normal cells. It further provides the induction of cell death by means of gene therapy. Apoptin can induce apoptosis in non-human animal tumor cells. The invention also provides that in normal cells apoptin was found predominantly in the cytoplasm, while in tumor cells it was located in the nucleus. Besides, the invention comprises a diagnostic test for the determination of cell-transforming activity.

Methods and uses for apoptin.

## BRIEF DESCRIPTION OF THE INVENTION.

The present invention relates to methods and uses for apoptin or derivatives or functional fragments thereof, whereby apoptin stands for the viral protein 3 (VP3) of

5 the chicken anaemia virus. It furthermore provides novel derivatives of said apoptin. Apoptin itself and its apoptosis inducing activity have been disclosed before (see below). However, in those earlier publications apoptin was no different from any other apoptosis inducing agent. We have now found that apoptin is indeed very different from other apoptosis inducing agents and may therefore be applied in different methods and for different uses. Whereas conventional apoptosis inducing agents induce apoptosis in any cell in which they are present we have now found that apoptin induces apoptosis only in transformed cells or tumor cells.

Thus the invention in one embodiment provides antitumor therapies. The application of apoptin as anti-tumor therapy will cause little toxicity for apoptin induces cell death to a high extent in tumor cells and much reduced if at all in normal non-transformed, non-malignant cells.

20

25

30

The invention also discloses that apoptin cannot be inhibited by several anti-apoptosis inhibitors. In particular, apoptin acts distinct from the p53-apoptotic pathway, which is known to be a necessary element in mediating apoptosis, which is triggered by a variety of (chemo)-therapeutic agents.

The invention further discloses the finding that apoptin can induce apoptosis in various types of mammalian tumor cells.

The invention further relates to differences in localization of apoptin in cells susceptible for apoptin-induced apoptosis, viz. human transformed and malignant

WO 96/41191

5

10

25

35

cells, versus cells insensitive to apoptin-induced apoptosis, viz. human normal cells. The differential location is used as diagnostic assay to analyse whether a cell is normal or has become transformed and/or malignant.

2

BACKGROUND OF THE INVENTION.

Jeurissen et al. (1992b) observed a number of phenomena in the thymi of chicken anemia virus (CAV)inoculated specific-pathogen-free chickens that were absent in thymi of control chicken. Ten days after infection, the entire cortex contained cells whose chromatin had condensed in areas adjacent to the nuclear membrane. More or less spherical electron-dense bodies were seen sporadically in the cytoplasm of epithelial 15 cells. At day 13 after infection, the cortex was severely depleted of thymocytes, whereas epithelial cells, many of them containing electron-dense bodies and other nonlymphoid cells were still present. DNA isolated from thymuses of chickens infected with various field isolates of CAV displayed the typical laddering of oligonucleosomal breakdown in an electropherogram. These observed morphological cellular and biochemical changes were also observed in CAV-infected cultured avian lymphoblastoid cells.

The above phenomena are characteristic of the physiological process of programmed cell death or apoptosis. Apoptosis is characterized by shrinkage of cells, segmentation of the nucleus, condensation and cleavage of DNA into domain-sized fragments, in most cells followed by internucleosomal degradation. Finally, the apoptotic cells fragment into membrane-enclosed bodies, which are rapidly phagocytosed by neighboring cells. Therefore, apoptosis causes much less destruction of tissue than necrosis, the non-physiological type of cell death (Wyllie et al., 1980, Arends and Wyllie, 1991).

Apoptosis is a cascade of events. In general, the apoptotic process can be devided in several stages.

Stage 1. Triggering of apoptosis.

Many different external and internal agents can trigger

the apoptotic process.

Stage 2. Factors which can mediate the apoptotic trigger.

A main role at this stage is played by e.g. the tumorsuppressor protein p53.

10

5

Stage 3. Enhancing of the apoptotic signal by factors as Bax.

Stage 4. Activation of the ICE serine-protease 15 family members.

As soon as these specific proteases are activated, the point of no return has been passed. Known apoptosis inhibitors as growth factors (inhibits at stage 2), Bcl-2 (stage 3) or crmA (stage 4) are known to inhibit

20 apoptosis at different stages during the decission stage of the apoptotic process

Stage 5. Execution of the apoptotic signal. For instance, DNA becomes condensed and

25 fragmented. (White, 1996).

Early after infection of cultured chicken mononuclear cells, the CAV-encoded protein apoptin (also called VP3) co-localizes with cellular chromatin. Later after infection, apoptin forms aggregates, the cells become apoptotic, i.e. the cellular DNA is fragmented and, as a result, becomes condensed (Noteborn et al., 1994). It was shown by immunogold electron microscopy that apoptin is present in apoptotic structures. In vitro, expression of apoptin in chicken transformed lymphoblastoid T cell and myeloid cell induced apoptosis in these cells. These data indicate that apoptin can trigger the apoptotic pathway in

10

30

35

CAV-infected cells (Noteborn et al. 1994, Noteborn and Koch, 1995).

Apoptin is a small protein, only 121 amino acids long, which is rather basic and proline-rich (Noteborn et 5 al., 1991). Apoptin is located strictly within the cellular chromatin structures. Truncation of the Cterminal basic stretch of apoptin results in a reduced nuclear location and a significantly reduced apoptotic activity (Noteborn et al., 1994). The small size and rather basic character of apoptin may allow it to interact with histone and/or non-histone proteins within the chromatin structure.

Apoptosis is an active and programmed physiological process for eliminating superfluous, altered or malignant cells (Earnshaw, 1995). The apoptotic process can be initiated by a variety of regulatory stimuli (Wyllie, 1995 and White, 1996). Changes in the cell survival rate play an important role in human pathogenesis, e.g. in cancer development, which is caused by enhanced cell 20 proliferation but also by decreased cell death (Kerr et al., 1994). A variety of chemotherapeutic compounds and radiation have been demonstrated to induce apoptosis in tumor cells, in many instances via wild-type p53 (Thompson, 1995, Bellamy et al., 1995, Steller, 1995, 25 Kaufman, 1989, McDonell et al., 1995, Lowe et al. and Fisher, 1994).

Many tumors, however, acquire a mutation in p53 during their development, often correlating with poor response to cancer therapy (Hooper, 1994). For several (leukemic) tumors, a high expression level of the protooncogene Bcl-2 is associated with a strong resistance to various apoptosis-inducing chemotherapeutic agents (Hockenberry, 1994, Kerr et al., 1994, Sachs and Lotem, 1993).

Apoptin can induce apoptosis human malignant cell lines (Noteborn and Koch, 1994). We have established that apoptin-induced apoptosis occurs in the absence of

5

functional p53 (Zhuang et al., 1995a), and cannot be blocked by Bcl-2 and BCR-ABL (Zhuang et al., 1995). Therefore, apoptin is usefulfor the destruction of tumor cells, which have become resistant to (chemo)therapeutic induction of apoptosis, due to the lack of functional p53 and (over)-expression of Bcl-2 and BCR-ABL.

#### DETAILED DESCRIPTION OF THE INVENTION.

10

15

20

25

30

35

The invention discloses the apoptotic activity of apoptin in (e.g.human) malignant and transformed cells versus normal cells. Apoptin fails to induce apoptosis in primary T cells, endothelial and smooth muscle cells. When normal cells are transformed they become susceptible by apoptin. In normal cells apoptin was found predominantly in the cytoplasm, while in tumor cell it was located in the nucleus.

Apoptin can be used for depletion of specifically transformed/malignant cells. Therefore, apoptin is a very potent anti-tumor agent. Expression of apoptin can be used for the induction of apoptosis in specifically (human) tumor cells. Apoptin does not or at least not significantly induce apoptosis in normal cells, indicating that the toxicity of apoptin-treatment will be low.

The invention discloses that apoptin is able to induce apoptosis in transformed, non-immortalized cells, which implies that the apoptotic activity of apoptin becomes already available during early transformation events in cells. Therefore, apoptin can be included in other (e.g. gene- or chemo-) therapies to prevent treated cells for undergoing transformation and even malignancy.

Apoptin can be (transiently) expressed in tumors by means of DNA transfection. Expression of apoptin in (tumor) cells may also take place by infecting cells with (retro)viral vectors that contain a coding sequence for apoptin.

Administration to cells of non-viral components (e.g. liposomes or transferrin-derived vectors) containing

10

15

30

35

apoptin proteins and/or coding sequence for apoptin is a further possibility for the expression/presence of apoptin and induction of apoptosis in tumor cells.

Furthermore, we have provided evidence that apoptin is distinct from the p53-induced apoptotic pathway. Besides the fact that apoptin does not need functional p53, apoptin cannot be blocked by inhibitors of the p53-apoptotic pathway, as the Bcl-2(-like) proteins, and the cow-pox protein crmA, which blocks the ICE-like protease activities. These inhibitors interfere within different stages of the p53-induced apoptotic cascade. Apoptin, might induce apoptosis completely independent from the apoptic pathway

blocked by these apoptotic inhibitors, or act downstream from them.

These data imply that apoptin is a very potent inducer of apoptosis in tumor cells, which can overcome (all analysed) blocks of anti-apoptotic activity in transformed

and malignant cells. Therefore, apoptin is a potent antitumor agent for a braod variety of tumor(s) (cells).

The differential localization of apoptin in normal versus transformed/malignant cells can be used as diagnostic test to distinguish whether a cell has become transformed/malignant.

Besides, the induction of apoptosis in human tumor cells, we have also provided evidence that apoptin can induce apoptosis in other mammalian tumor cells. The invention can be used for treatment of cancer in various mammalian sytems.

Thus the invention provides a vehicle delivering a tumoricidal substance or a gene encoding a tumoricidal substance mainly but not exclusively with a tumor cell, characterized in that the tumoricidal substance is apoptin or a functional equivalent thereof. In the prior art many vehicles for delivering cytotoxic agents or precursors therefor have been disclosed. A major problem in

7

delivering cytotoxic agents is that they are harmful to all cells and not just the tumor cells (which will be interchangeably called transformed or malignant or tumor cells herein). Therefore many different ways of targetting 5 the cytotoxic substance to the tumor cells have been investigated. Although many targetting moieties are nowadays known, all of them suffer from the drawback of not being completely specific for the tumor target. Therefore the use of this cytotxic substances has sofar not met with great success. At the time of its discovery apoptin was thought to suffer from the same drawback in that it would need a highly specific targetting moiety. We have now found that this is not necessary for apoptin. Apoptin only has a significant effect in tumor cells and not in normal cells. Thus, even if the targetting moiety or any other means of delivery of apoptin (or a functional equivalent) is not very specific, this will result in hardly any toxicity to normal tissue. Thus the invention provides a conjugate for targeted tumor therapy comprising a targeting moiety having binding affinity for a molecule associated mainly, but not exclusively with the surface of a tumor cell and apoptin or a functional equivalent thereof. A functional equivalent of apoptin is any fragment or derivative having the same kind of activity, possibly in different amounts.

10

15.

20

25

30

A targetting moity is well defined in the art as a molecule with a specific binding activity for a target molecule. It should preferably be capable of internalization. The target molecule may be an antigen or an epitope, in which case the targetting moity is an antibody or a fragment or a derivative thereof. The target molecule may be a receptor in which case the targetting moiety is a ligand for said receptor. These are just examples of suitable combinations. The bond between the targetting moiety and the apoptin has only one requirement in that it should allow the functions of both partners to operate. Thus, it may be a chemical (labile) bond, it may

8

be a fusion protein. The conjugate may even be a liposome covered with targetting moieties and filled with apoptin (or a gene encoding it) etc. The invention also comprises a vehicle delivering a gene encoding apoptin to a tumor cell, using gene therapy. Gene therapy has many well known methods to deliver genes to cells using viruses such as adenovirus or retrovirus. The person skilled in the art will know how to select the right vehicle. Because apoptin only functions to induce apoptosis in transformed cells, it or its gene can be used as a safety measure in other gene therapy regimens than tumor therapy; such as those rectifying deficiencies from inheritable diseases. It is then provided in a gene delivery vehicle together with the gene of interest and if the cell in whhich the gene of interest is inserted becomes malignant then it will be susceptible to the action of apoptin. Thus the invention provides a vehicle for delivering a nucleic acid of interest to a target cell, said vehicle further comprising a gene encoding apoptin or a functional equivalent thereof.

10

15

20

25

30

Since this is the first really feasible medical use of apoptin such a use is also part of the present invention. Thus there is provided apoptin or a functional equivalent thereof for use in a method of eliminating cells of a target cell population whereby the method is mainly, but not entirely specific for the cells of the target population, whereby apoptin or its functional equivalent is the ctotoxic agent, as well as apoptin or a functional equivalent thereof for use in a method of eliminating cells of a target cell population whereby the cells of said population are not sensitive to other apoptosis inducing agents.

The latter is possible because apoptin cannot be inhibited by the mechanims inhibiting the other apoptosis inducing substances. If apoptin is to be used to eliminate cells that are not transformed then this can be achieved by providing apoptin or a functional equivalent thereof

9

provided with a nuclear localization signal. Since apoptin needs to be in the nucleus this will result in apoptosis. Without said signal the apoptin would remain outside the nucleus and have no significant effect (as disclosed herein).

Thus said apoptin with a nucleus localization signal could be used in a method for elimination of cells of a population of target cells. Nuclear localization signals (NLS) are well known in the art. One could also provide a fusion gene encoding an NLS and an apoptin.

Because apoptin has a different localization in normal cells as compared to in transformed cells, it is possible to use apoptin as a diagnostic tool distinguishing between those two kinds of cells. Thus the invention also provides a method for distinguishing between transformed and/or malignant and/or tumor cells and normal cells comprising the steps of providing said cells with the viral protein 3 (VP3; apoptin) and detecting the localization of said viral protein in said cells. The localized apoptin can be detected with e.g. antibodies.

The invention will be explained in more detail on the bassis of the following experimental part. This is only for the purpose of illustration and should not be interpreted a a limitation of the scope of protection.

#### EXPERIMENTAL

10

15

20

25

### Isolation of human primary cells.

Human primary T cells were isolated from 6 normal blood donors by Ficol centrifugation and grown in RPMI-medium containing 6% human serum and 0.8 ug per ml phytohemagglutinin. After 3 days the medium was refreshed and 300 units per ml Interleukin-2 was added. Human primary smooth-muscle cells (SMC) and vascular endothelial cells (HUVEC) were isolated from umbilical cords. SMC were

10

20

25

grown in CM199 medium supplemented with ECGF and heparine and HUVEC in DMEM medium containing 10% fetal calf serum.

#### DNA plasmids.

5 All CAV DNA sequences are originally derived from the plasmid DNA pIc-20H/CAV-EcoRI (Noteborn and De Boer, 1990). All cloning steps with plasmid DNAs were in principle carried out according the methods by Maniatis et al: (1982).

The expression plasmid pCMV-fs, formerly called pCMV-VP3, contains CAV DNA sequences encoding apoptin exclusively (nt 427-868), plasmid pCMV-tr encodes a truncated apoptin which lacks the C-terminal 11 amino acids (Zhuang et al., 1995a), and pCMV-des encodes desmin, a structural protein found in muscle cells that does not 15 induce apoptosis (Menke et al., unpublished data). The expression plasmids pCMV-BAG-1 (Noteborn, M.H.M., unpublished data), pCMV-BcL-2 (Zhuang et al., 1995b) and pCMV-crmA (Noteborn, M.H.M., unpublished data) expresses the anti-apoptosis proteins BAG-1, Bcl-2 and the cowpox crmA protein inhibiting ICE-like proteases, respectively. The expression plasmids pCMV-E1B21K expresses the adenovirus E1B 21kDa protein and pCMV-p53, the tumor supressor protein p53 (Zhuang et al., 1995).

All transiently expressed genes are under the regulation of the cytomegalovirus promoter.

## Human normal, transformed and malignant keratinocytes and fibroblasts.

30 Human keratinocytes were isolated from foreskin and grown in the presence of a layer of mouse 3T3 fibroblasts lethally irradiated with 137Cs. Primary cultures of human epidermal keratinocytes (FSK-1) were initiated in complete medium as described (Rheinwald and Green, 1975) with minor 35 modifications.

11

Human normal foreskin diploid VH10 fibroblasts (Klein, 1990) were grown in DMEM supplemented with 10% fetal-calf serum.

SV40-transformed tumorigenic NW18 fibroblasts (Weissman and Stanbridge, 1983) were grown in MEM medium supplemented with 8% fetal calf serum.

Tumorigenic keratinocytes, SCC-15 (Rheinwald and Beckett, 1981), derived from squamous-cell carcinoma, were cultured in DMEM/F12 (3:1) medium containing 5% fetal-calf serum, 0.4 ug per ml hydrocortisone and 1 uM isoproterenol.

The SV40-transformed fibroblasts, pre-crisis (Pre) and post-crisis (Post), as described by B. Klein et al. (1990) were grown in MEM medium with 8% fetal-calf serum.

The spontaneously transformed keratinocyte strain HaCaT (Boukamp et al., (1988) was a gift from Prof. Dr. Fusenig, DKFZ, Heidelberg, Germany. HaCaT cells were grown in DMEM medium supplemented with 10% fetal-calf serum. The SV40-transformed keratinocyte strain SVK14 (Taylor-Papadimitriou et al., 1982) cells were cultured in the

## DNA transfections.

same medium as SCC-15 cells.

10

25

30

Plasmid DNA was purified by centrifugation in a CsCl gradient and column chromatography in Sephacryl S500 (Pharmacia).

Phytohemagglutinin-stimulated primary human T cells were transfected in the presence of DEAE-dextran, as described (Noteborn et al. 1994). Mouse Crip cells and human Hep3B, VH10, Pre- and Post-, and NW18 cells, HUVECs and SMCs were transfected with plasmid DNA by calcium-phosphate precipitation as described (Graham and Van der Eb, 1973). FSK-1, HaCaT, SVK14 and SSC-15 cells were transfected with DOTAP [D.Fischer, unpublished results]

#### Immunofluorescence

T cells were grown in suspension and fixed on glass microscope slides. All other cells were grown on coated glass microscope slides. The cells were fixed with 80% acetone for 10 min at room temperature, and used for indirect immunofluorescence as described (Noteborn et al., 1994). To demonstrate the presence and/or cellular location of (truncated) apoptin in transfected cells mouse monoclonal antibodies (MAb) CVI-CAV-85.1 (85.1) (Noteborn et al., 1991) and CVI-CAV-111.3 (111.3; Koch, unpublished data) were used and for human desmin the mouse MAb 33 (Monosan, Uden, The Netherlands) was used. Fluoresceinisothiocyanate-labeled goat anti-mouse antibodies (Jackson Immunoresearch Laboratories Inc., West Grove PA) were used as second antibodies. Nuclear DNA was stained with 2,4-diamidino-2-phenylindole (DAPI) or propidium iodide (PI).

## Stable DNA tranfection of VH10 cells.

Human normal diploid VH10 fibroblasts were stably transfected with pCMV-fs, expressing full-sized apoptin or pCMV-neo-Bam, the empty plasmid without the CAV sequences encoding apoptin. Stable clones were selected with G418 medium, grown on glass microscope slides and fixed with 80% acetone. Expression of apoptin was analysed by indirect immunofluorescence using MAD 85.1.

#### RESULTS AND DISCUSSION

## 30 Expression of apoptin in mouse tumor cells in vitro.

We have examined whether apoptin can induce apoptosis also in mammalian tumor cells of non-human origin.

Therefore, cells of the mouse tumor cell line Crip (Danos, 1988) were transfected with pCMV-fs DNA encoding apoptin. Three days after transfection the cells were fixed. By means of immunofluorescence and PI staining the cells were examined for expression of apoptin, and whether they

10

15

20

25

30

became apoptotic. Already, at three days after transfection 54% of the mouse tumor cells, which contain apoptin, have become apoptotic.

These results indicate that apoptin can induce apoptosis in different mammalian tumor cell lines.

# In Hep 3B cells apoptin-induced apoptotic pathway is distinct from the p53-induced apoptotic pathway.

Recently, we have shown that apoptim induces apoptosis in osteosarcoma cells, without the presence of wild-type p53 (Zhuang, et al., 1995, Noteborn and Koch, 1994). Chiou et al. (1994) and Debbas and White (1993) have provided evidence that Bcl-2 and adenovirus 5 (Ad 5) E1B 21K protein can block p53-induced/mediated apoptosis by acting downstream from p53.

We examined whether Ad 5 ElB 21K protein and Bcl-2 can inhibit the p53-independent pathway of apoptosis induced by apoptin in comparison to p53-dependent apoptosis. To that end, we studied the effect of co-expression of these proteins with apoptin or p53 in the human hepatoma Hep3B cell line.

Hep3B cells were co-transfected with pCMV-fs, encoding apoptin and pCMV-neo-Bam DNA (negative control), pCMV-E1B21 DNA, encoding the Ad5 E1B 21K protein or pCMV-Bc12 (Zhuang et al., 1995b), encoding human Bc1-2. The number of apoptin-expressing cells was screened by indirect immunofluorescence and by DAPI-staining, which is weak and/or irregular when the cells have become apoptotic.

Surprisingly, at several timepoints after transfection the percentage of apoptin-expressing Hep3B cells, which became apoptotic was similar to the Hep3B cells containing both apoptin and ElB-2lK or both apoptin and Bcl-2. For the sake of brevity, only the data obtained six days after transfection are given in Figure 1.

To illustrate that E1B-21K or Bcl-2 indeed have an anti-apoptotic effect in Hep3B cells, we examined whether

14

these two proteins could inhibit apoptosis caused by over-expression of p53 in Hep3B cells. Compared to cotransfection of Hep3B cells with pCMV-p53 DNA encoding wild-type p53 (Baker et al., 1990) and pCMV-neo-Bam, cotransfection with plasmids pCMV-p53 and pCMV-E1B21, or pCMV-Bcl2 resulted in a significant reduction of apoptosis induced by p53, as analysed by immunofluorescence and PI-staining (Figure 2).

Thus, absence of effect of E1B 21K and Bc1-2 proteins on apoptin-induced apoptosis can not be explained by non-functionality of the expressed proteins in Hep3B cells for they can inhibit p53-induced apoptotic pathway. The fact that E1B 21K and Bc12 still could negatively influence the p53-regulated apoptotic pathway in Hep3B cells, although the apoptin-induced apoptosis could not be inhibited indicates that the p53-dependent and apoptin-inducable p53-independent apoptotic pathway are distinct routes at least within Hep3B cells.

The fact that in a large number of tumors apoptosis cannot be induced in a variety of chemotherapeutic agents seems to be related to disrupted functions of p53 (Lowe et al., 1993). Therefore, induction of a p53-independent apoptotic pathway is a useful approach as alternative for tumor therapy.

25

30

35

10

15

20

# Characterization of the apoptin-induced apoptotic pathway in Saos-2 cells.

The apoptin-induced apoptotic pathway seems to be distinct from that induced by p53 (see above). Bcl-2, known to be involved in tumorformation via inhibition of the apoptotic pathway, could not block apoptin-induced apoptosis, but could block the p53-pathway. Recently, it has been reported by others that Bcl-2 and Bag-1 (Takayama et al., 1995) together might be required for the inhibition of so-called Bcl-2-independent apoptosis, as seems to be the case for apoptin-induced apoptosis.

do not or only use a very minor part of the p53-induced apoptotic pathway.

## Expression of apoptin in normal human cells.

5 Three types of human primary cells, i.e. vascular endothelial cells (HUVEC), smooth muscle cells (HSMC) and T cells, were transiently transfected with a plasmidencoding full-sized apoptin (pCMV-fs). Cells expressing apoptin were screened via indirect 10 immunofluorescence with MAb 85.1[8] or 111.3. Induction of apoptosis in apoptin-positive cells, was analysed with the help of DAPI or PI, which stain intact nuclei regularly, but apoptotic ones irregularly and/or weakly (Telford, 1992). Five days after transfection, only around 15 20% of the apoptin-expressing primary cells stained abnormally with DAPI or PI (data not shown). Menke et al. (unpublished) data have reported for another apoptosis system that this low percentage DAPI-abnormal cell is not due to a specific apoptosis-inducing agent, but due to 20 transfection events. Also, the experiments shown below prove this statement. In similar experiments, 60-90% of malignant cells containing apoptin were apoptotic [Zhuang et al., 1995, 1995a,b). The localization of apoptin in these primary cells also differed from the localization in 25 tumor cells. In all of the normal cells, apoptin was found in the cytoplasm, and not in the nucleus as has been observed for various tumor cell lines (Zhuang et al., 1995, 1995a,b). These results suggest that apoptin fails to induce apoptosis in various cultured human non-30 transformed, non-tumorigenic cells, and that the cellular location of apoptin is important for its apoptotic activity.

· Our observations show that apoptin does not induce apoptosis in normal fibroblasts and keratinocytes, but does in their tumorigenic derivatives.

#### Expression of apoptin in human transformed cells.

Is tumorigenicity required for apoptin to induce cell death, or is mere transformation of a cell sufficient? To answer this question we have examined the effect of apoptin in transformed, non-tumorigenic fibroblasts and keratinocytes. Apoptin, truncated apoptin, and desminwere 10 transiently expressed in SV40-transformed fibroblasts, prior (Pre) or post (Post) immortalization, in SV40transformed and immortalized SVK14 keratinocytes, and in spontaneously transformed HaCaT keratinocytes. Apoptin was able to induce apoptosis in all these types of transformed cell, to an extent similar to that in tumor cells (Figures 5 and 6). The percentage of cells containing (truncated) apoptin which had become apoptotic was significantly higher than in desmin-positive cells. These data imply that apoptin can induce apoptosis in both malignant and transformed cells.

Some chemotherapeutic agents and radiation can induce apoptosis in transformed cells but fail to do so in untransformed cells (Thompson, 1995, McDonell et al., 1995). Transformation seems to cause changes that make a 25 cell more sensitive to apoptotic stimuli. Some other proteins are known to kill tumor cells specifically. The parvovirus structural protein NS-1 induces cell lysis specifically in neoplastic cells (VanAcker and Rommelaere, 1995). Also, a bcl-xs-expressing adenovirus has been 30 constructed that induces apoptosis in human breast- and colon-carcinoma and neuroblastoma cells, but not in human normal hematopoietic cells or in the human leukemia cell line K562 (Clarke et al., 1995).

Stable transfection of VH10 cell with a plasmid ecoding apoptin.

19

To exclude that apoptin has a minor but significant apoptotic activity in normal VH10 cells, these cells were stably transfected with pCMV-fs or with pCMV-neo-Bam as a control. We obtained a similar amount of colonies in both transfections. The resulting cells, stably transfected with pCMV-fs, expressed apoptin which was located in the perinuclear region (data not shown). Therefore, it can be concluded that apoptin cannot induce apoptosis or inhibit the growth of normal VH10 cells in any other sense.

# Cellular localization of apoptin in normal versus transformed and malignant cells.

15 Apart from the different apoptotic activities of apoptin in malignant and transformed cells versus normal cells, we have also observed differences in the cellular localization of apoptin in these cell types. In transformed and malignant cells, before the apoptotic 20 morphological changes are oticeable, apoptin is, distributed as fine granules, mainly in the nucleus. After the cells had undergone apoptosis, apoptin was aggregated in the nucleus. In contrast, the location of apoptin in normal fibroblasts and keratinocytes is mainly in the 25 cytoplasm, concentrated round the nucleus, both as small granules and larger aggregates. In primary HUVECs, HSMCs and T cells, apoptin was also localized in these characteristic perinuclear structures. Thus far, in all malignant or transformed cell lines studied, apoptin had a 30 nuclear location, whereas in all normal cells analysed thusfar, it had not.

Others have proposed that transformed cells have undergone loss-of-function mutations, as a result of which a normally functioning inhibitor has been switched off. Due to these changes, nuclear transport of proteins may be promoted or hindered in cancer cells (Csermely et al., 1995). It is possible that in normal cells apoptin is

WO 96/41191

associated to and/or modified by one or more cellular factor(s), resulting in its location within perinuclear structures. The loss of such (functional) factor(s) in malignant cells might allow apoptin to enter the nucleus.

20

PCT/NL96/00229

Apoptin harbors not only putative nuclear-import sequences (Noteborn et al., 1991, 1994, 1995, Zhuang et al., 1995, 1995a,b, but also an amino-acid region resembling nuclear export signals (position 33-46: IRIGIAGITITLSL), similar to that of the protein kinase inhibitor (PKI) and the HIV-Rev protein ( Wen et al., 1995, Fischer, et al., 1995, Gerace, 1995). It might well be that this potential nuclear export signal cannot be recognized in the various analysed malignant and transformed cell lines.

15 The results described here indicate that the nuclear localization of apoptin is important for its ability to induce apoptosis. This is in agreement with the observation that truncated apoptin, which has a reduced apoptotic activity (Figures 5 and 6), is partially in the 20 cytoplasm. Electron microscopic studies with chicken mononuclear cells revealed that apoptin co-localizes with the cellular chromatin (Noteborn et al., 1994). The interaction of apoptin with chromatin could result in unwinding of its superstructure. The latter phenomenon has 25 been described for rat ventral prostate cells, which became apoptotic after castration of the rats (Kyprianou and Isaacs, 1989).

### Apoptin as an anti-tumor agent.

30 Our results indicate that apoptin is an anti-tumor agent. Firstly, apoptin is specifically active in malignant and transformed cells, but, at least in vitro, not in the normal cells tested. Therefore, the toxic effect of apoptin treatment might be very low. Secondly, apoptin induces apoptosis in a p53-independent manner. The fact that several chemotherapeutic agents lose this capacity to induce apoptosis in a large number of tumors

21

seems to be related to a disruption of p53 function. Therefore, induction of a p53-independent apoptotic pathway might be a useful approach as an alternative candidate for tumor therapy. Furthermore, apoptin apparently is not blocked by Bcl-2, which is known to be involved in the development of, e.g., leukemic tumors and which can inhibit apoptosis induced by chemotherapeutic agents. In addition, we have observed that BAG-1, a Bcl-2-related protein, is not able to block apoptin-induced apoptosis.

#### Description of the figures

Figure 1 shows the effect of expression of E1B-21kD and Bc1-2 on the induction of apoptosis by VP3 in p53-minus Hep3B cells. The percentage given is that of the apoptin-positive cells which are apoptotic 6 days after transfection. The cells were co-transfected with 2.5 ug of pCMV-VP3 and 5 ug of pCMV-neo-Bam (open bars), 5 ug of pCMV-E1B21 (hatched bars), or 5 ug of pCMV-Bc12 plasmid DNA (dotted bars). At least 3 independent experiments were carried out. Per experiment at least 200 apoptin-positive cells were examined.

Figure 2 shows the effect of E1B-21K and Bcl-2 proteins on the induction of apoptosis by p53 in the Hep3B cell line. The cells were co-transfected with 2.5 Eug of pCMV-p53 and 5 Eug of pCMV-neo-Bam, 5 ug of pCMV-E1B21K, or 5 ug of pCMV-Bcl2 plasmid DNA. Two independent transfections were carried out. The cells were analysed 4 or 5 days after transfection. The percentage given is that of p53-positive cells which are apoptotic. Per experiment at least 200 p53-positive cells were examined.

Figure 3 shows the effect of Bcl-2 and Bag-1 expression on the p53-induced apoptosis or apoptin-induced apoptosis. Saos-2 cells were co-transfected with 2.5 ug of pCMV-fs, and 5 ug of pCMV-Bcl-2, pCMV-Bag-1, or PCMV-Bag-1 and pCMV-Bcl-2. In a parallel experiment, the cells were co-transfected with 2.5 ug of pCMV-p53 and 5 ug

22

pCMV-Bcl-2, pCMV-Bag-1 or pCMV-Bag-1 and pCMV-Bcl-2. As controls, pCMV-p53 or pCMV-fs were co-transfected with pCMV-neo-Bam. At least, 3 independent experiments of both series were carried out. The cells were harvested 4 days after transfection. The percentage is given of the p53- or apoptin-positive cells which have become apoptotic. Per experiment at least 200 cells have been examined.

Figure 4 shows the effect of the ICE-inhibitor crmA on the induction of p53- or apoptin-induced apoptosis. Saos-2 cells were co-transfected with 2.5 ug pCMV-fs and 5 ug pCMV-crmA (+crmA) or pCMV-neo-Bam (-crmA). In parallel, cells were co-transfected with 2.5 ug pCMV-p53 and 5 ug pCMV-crmA or pCMV-neo-Bam. Two independent experiments were carried out. The cells were harvested 5 days after transfection. The percentage is given of the p53- or apoptin-positive cell which have become apoptotic. Per experiment, at least 200 positive cells were examined.

Figure 5 shows the apoptin activity in normal versus transformed or malignant human fibroblasts. The percentage of cells that stained abnormally with DAPI is given as a relative measure for apoptosis in normal VH10 versus transformed (Pre, Post) and tumor (NW18) fibroblasts, transiently transfected with pCMV-fs, pCMV-tr or pCMV-des. Cells were fixed five days after transfection and analysed by indirect immunofluorescence. Results are the means of at least three independent experiments. In each experiment, at least 200-full-sized or truncated apoptinor desmin-positive cells were examined. Cells were fixed 5 days after transfection and analysed by indirect immunofluorescence.

Figure 6 shows the apoptin activity in normal versus transformed or malignant keratinocytes. The percentage of cells that stained abnormally with DAPI is given as a relative measure for apoptosis in normal keratinocytes (FSK-1) versus transformed (SVK14, HaCAT) and tumor (SCC-15) ones, transiently transfected with pCMV-fs, pCMV-tr, or pCMV-des. Cells were fixed five days after transfection

23

and analysed by indirect immunofluorescence. Results are the means of at least three independent experiments. In each experiment, at least 200-full-sized or truncated apoptin- or desmin-positive cells were examined.

#### CLAIMS

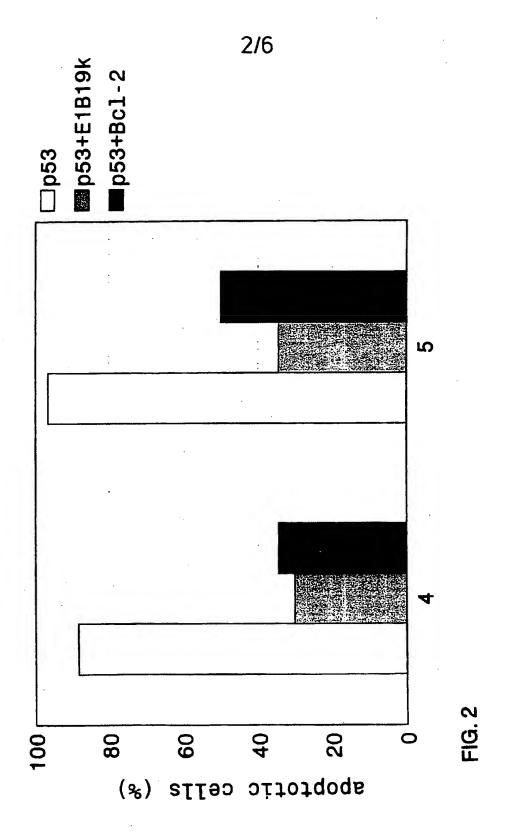

- 1. A method for distinguishing between transformed and/or malignant and/or tumor cells and normal cells comprising the steps of providing said cells with the viral protein 3 (VP3; apoptin) and detecting the localization of said viral protein in said cells.
- 2. A vehicle for delivering a nucleic acid of interest to a target cell, said vehicle further comprising a gene encoding apoptin or a functional equivalent thereof.
- 3. A conjugate for targeted tumor therapy comprising a targeting moiety having binding affinity for a molecule associated mainly, but not exclusively with the surface of a tumor cell and apoptin or a functional equivalent thereof.
- 4. A vehicle delivering a tumoricidal substance or a

  15 gene encoding a tumoricidal substance to a molecule
  associated mainly but not exclusively with a tumor cell,
  characterized in that the tumoricidal substance is apoptin
  or a functional equivalent thereof.
- 5. Apoptin or a functional equivalent thereof for use in a method of eliminating cells of a target cell population whereby the method is mainly, but not entirely specific for the cells of the target population, whereby apoptin or its functional equivalent is the ctotoxic agent.
- 6. Apoptin or a functional equivalent thereof for use in a method of eliminating cells of a target cell population whereby the cells of said population are not sensitive to other apoptosis inducing agents.
  - 7. Apoptin or a functional equivalent thereof provided with a nuclear localization signal.
- 8. Apoptin or a functional equivalent according to claim 8 for use in a method for elimination of cells of a population of target cells.
  - 9. A nucleic acid encoding an apoptin or a functional equivalent thereof according to claim 8.

rnational application No.

PCT/NL96/00229

Box ( Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This international search report has not been established in respect of certain claims under Article 17(2)(2) for the following reasons:
1. X Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely: Please see Further Information sheet enclosed.
2. Claims Nos.:  because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)
This International Searching Authority found multiple inventions in this international application, as follows:
As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searches without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
Remark on Protest  The additional search fees were accompanied by the applicant's protest.  No protest accompanied the payment of additional search fees.

## FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

Remark: Although claim 1 (partially, in so far as the method is carried out in vivo) is directed to a diagnostic method practised on the human/animal body the search has been carried out and based on the alleged effects of the compound.
